TITLE: Complex heat exchange and hydraulic drag in a moving gray fluid with high optical density

SOURCE: Moscow. Institut inzhenerov zheleznyodorozhnogo transporta. Trudy, no. 189, 1965. Issledovaniye teploobmena v teploenergeticheskikh ustanovkakh i v ustanovkakh dlya polucheniya poluprovodnikovykh materialov (Investigation of heat exchange in thermal power units and in equipment for producing semiconductor materials), 41-52

TOPIC TAGS: thermodynamic analysis, heat exchange, grey body, optical density, boundary layer, laminar flow

ABSTRACT: This article examines the problem of complex heat exchange and hydraulic drag in a moving gray fluid with high optical density. Let a stream of incompressible gray fluid with high optical density strike a plate with velocity  $w_0$  (see fig. 1 of the Enclosure). Near the surface of the plate a laminar boundary layer is formed of thickness  $\delta = \delta(x)$ . During nonisothermal motion of a medium with temperature  $T_0$  a temperature boundary layer  $\delta_T = \delta_T(x)$  is also formed near the wall. Physi-

Card 1/3

ACCESSION NR: AT5016480

cal characteristics of the medium: density  $\rho$ , coefficient of heat conductivity  $\lambda$ , coefficient of absorption  $K$ , coefficient of kinematic viscosity  $\nu$  are assumed constant. Transfer of heat energy in the gray fluid is determined by convective and radiant components. Because of this, the energy equation must be completed by a term which takes account of radiant heat exchange. These considerations are used in setting up laminar boundary layer equations. On the basis of these equations calculated relationships are derived for hydraulic resistance and heat exchange during movement of gray fluids. Variation in the optical density of the fluid to a significant degree determines the value of the radiation components of the complex heat exchange. Analysis of the solutions shows that hydrodynamics is a determining factor for intensification not only of convective but also of complex heat exchange. For gray fluids with very high optical density the share of radiant transfer of energy is diminished. Orig. art. has: 1 figure, 35 formulas.

TITLE: Convective heat exchange in the case of eddy of a viscous fluid at the initial section of a tube

SOURCE: Moscow. Institut inzhenerov zheleznodorozhnogo transporta. Trudy, no. 189, 1965. Issledovaniye teploobmena v teploenergeticheskikh ustanovkakh i v ustanovkakh dlya polucheniya poluprovodnikovykh materialov (Investigation of heat exchange in thermal power units and in equipment for producing semiconductor materials), 83-90

TOPIC TAGS: heat exchange, turbulent flow, thermodynamic analysis

ABSTRACT: This article examines convective heat exchange at the entrance region of a cylindrical tube and on the basis of integral equations presents a solution which agrees closely with existing experimental data. Calculations and graphs are presented. Some deviation from the experimental data results from the fact that, in this paper, allowance is made for the turbulent layer formed at the very beginning of the tube. In actuality, during an eddy flow near the entrance region, a laminar boundary layer is formed which becomes turbulent only after a certain distance.

TOPIC TAGS: geophysic research facility, meteorologic research facility, Antarctic climate, oceanographic ship

ABSTRACT: This article describes the staffing and equipping of the new Soviet station Molodezhnaya in Enderby Land. The program of scientific works for the new station included meteorological and actinometric observations, radiosonde observations of the atmosphere, hydrological observations, and observations of terrestrial magnetism, including a continuous recording of the variations of the geomagnetic field and absolute determinations. The personnel, equipment, and everything necessary for the initial organization of the station were landed

by two aircraft and on February 23, 1962, this operation, which took two days, was completed. In all there were 15 aircraft runs and more than ten tons of cargo unloaded. On the next day the radio station was set up for direct communication with Mirnyy and Novolazarevskaya and the meteorological station equipped. By 10 March the construction of the scientific buildings for aerological and magnetic observations was completed. After a long and difficult passage through the ice the ship Ob' finally moored on March 18 at a natural wharf (ice barrier). On March 31, 1962 the team went aboard the Ob' to return home, leaving 12 men to spend the winter at the new station. Orig. art. has: 1 figure.

## TABLE OF CONTENTS:

Kostylev, K. V., Yu. A. Pupyshev, and V. V. Sidorov. Equipment Used at the Astronomical Observatory imeni Engel'gardt for Radar Observations of Meteors 1  
The authors describe the registration unit used in conjunction with the Observatory's three KGY-M1 radar installations to record on film both basic data on meteor activity and the distribution of radio echoes according to three amplitude levels. A schematic diagram of the photo attachment shows the unit to consist of three parts: 1) signal group (basic unit which detects signal, chooses first-level amplitude, selects width, and forms pulse of selected signal which then proceeds to the electron-ray tube modulator of the recording oscilloscope; 2) scan group (scan and trigger on a twin triode fixes meteor reflection on the film in the form of a double point); and 3) the service group (records time, distance, and other data). A block diagram is given of an additional unit used to obtain information on the static distribution of the amplitudes of the radar

TITLE:

On the electron distribution along the radius of a meteor trail

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiofizika, v.5, no.2, 1962, 216-220

TEXT: No direct measurements of the radial electron density distributions in meteor trails have been carried out. The two-frequency method now discussed is said to be suitable for this purpose. In this method two coherent transmitters operating at frequencies  $\nu$  and  $2\nu$  are employed ( $\lambda = 4-10$  m). Since the two components are reflected at different depths in the meteor trail (provided it is dense enough for these reflections to occur), it is possible to determine the corresponding path difference in the trail and hence deduce the electron density distribution. In practice, the delay of the signal at  $2\nu$  is measured relative to the signal at  $\nu$ . The theory of the method is developed and the formulae for the trail parameters are derived for exponential, Gaussian and linear distributions.

ABSTRACT: The pulse-Doppler section of the meteor station KGU-M2 is described. The "sector" method of recording makes it possible to measure Doppler frequency shifts by determining the speed of rotation of the phase-meter measuring vector relative to the reference signal. It is increases by a factor of almost two the number of meteor reflections suitable for the study of drifts. The influence of diffraction and polarization phenomena on the measurement accuracy is considered. [Translation of abstract]

TITLE: The use of a phase technique in studies of polarization phenomena associated with radio wave reflection from meteor trails

SOURCE: IVUZ. Radiofizika, v. 8, no. 2, 1965, 234-243

TOPIC TAGS: radio wave reflection, meteor trail, polarization phenomenon, circular polarization antenna

ABSTRACT: Polarization phenomena associated with radio wave reflections from meteor trails are studied by comparing the signal phases in a weakly directional circularly polarized antenna using a direct phase method. This technique makes it possible to separate polarization phenomena from diffraction and wind effects and to observe polarization phase shifting in radio wave reflections of all types regardless of duration. A method of indicating polarization phenomena in observations of meteor trail drifts is proposed; it is noted that the existing theory of polarization phenomena in saturated trails, based on the

Card 1/2

L 53796-65  
ACCESSION NR: AP5014500

assumption of a "metallic" trail model, does not fully explain the polarization phenomena observed in regions of transition to denser trails. It is concluded that if the Earth's magnetic field is responsible for the anisotropy observed in the trails, which produces prolonged reflections, then the trail structure should be less saturated than that encountered in the case of ambipolar diffusion.

TITLE: Continuous emission apparatus for measuring the wind velocity profile at meteor altitudes

SOURCE: Ref. zh. Astronomiya, Abs. 1.51.378

REF SOURCE: Sb. Meteorn. rasprostr. radiovoln. No. 2. Kazan', Kazansk, un-t, 1964, 59-70

TOPIC TAGS: meteor observation, meteor radiant, meteor trail, wind velocity

ABSTRACT: A radio device was developed which uses continuous emission for measuring the wind velocity profile in the meteor region of the atmosphere according to shifts of several portions of the meteor track spaced in altitude. The installation comprises the ~~meteor station~~ KGU-M2, operates together with its pulsed part, and at the same time can be used for measuring the velocities and radiants of meteors. The design equations are presented. The problem of determining  $t_0$  is discussed. Abstract /Translation of abstract/

TITLE: Atmospheric motions at altitudes of 80--100 km as determined by radio observations of meteors in Kazan'

SOURCE: AN SSSR. Izvestiya. Fizika atmosfery i okeana, v. 3, no. 1, 1967, 3-15

TOPIC TAGS: ~~atmosphere~~, atmospheric disturbance, atmospheric circulation, wind velocity, radar observation, meteor observation

ABSTRACT: Data on the yearly cycle of wind velocity variations at altitudes of 80-100 km obtained from radar observations of meteors are presented.

Harmonic analysis of atmospheric motion was made considering the statistical weights of mean hourly velocity values. It was concluded that in 1964 the total atmospheric circulation intensity was lower than during previous years, although basic features relevant to directional changes in air motion remained the same. During winter months, an increase in turbulence

Card 1/2

UDC: 551.55:551.510.535.4

ACC NR: AP7006176

intensity occurred simultaneously with an increase in the amplitude of diurnal turbulence variations. The characteristic horizontal extent of large-scale turbulences was found to be about 20 km as compared with 100 to 200 km reported earlier by other researchers. TITLE: A method for measuring the parameters of meteor trains. Class 21, No. 169591

qm

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 7, 1965, 42

TOPIC TAGS: meteor study

ABSTRACT: This Author Certificate presents a method for measuring the parameters of meteor trains using two-frequency coherent probing. In order to broaden the range of measurements on over-dense trains of meteors, the measurements of the initial radius, linear electron density, and coefficient of atmospheric diffusion at the image point are made on the basis of phase relationship for four arbitrary moments of time (see Fig. 1 on the Enclosure). Orig. art. has: 1 figure.

TITLE: The Body Cavity of Argas Ticks as the Habitat of Spirochetes and Brucella

PERIODICAL: Zhurnal mikrobiologii, epidemiologii i immunobiologii, 1960, No. 6, pp. 91 - 97

TEXT: A study was made of Argas ticks, their defense mechanism and interaction with invading causative agents of various diseases. The main form of immunity in the Ornithodoros lahorensis, Ornithodoros papillipes and Argas persicus ticks was the phagocytic activity of the tissue cells of their internal environment, and especially the phagocytic powers of the hemolymph. Agglutinins were detected in Argas persicus ticks capable of agglutinating a vaccinal 19-BA strain of Brucellus abortus. This mechanism was usually effective if the causative agents, such as spirochetes or Brucella, managed to overcome the barriers imposed to entry into the tick's intestine by: the pH of the intestinal contents, digestive enzymes, bacteriolsins, temperature differences or the mechanical barrier of the intestinal wall. An incomplete form of phagocytosis of Brucella by the tick's amebocytes was noted, whereby the Brucella were transformed into amebocytic

Card 1/2

S/016/60/000/06/23/051

The Body Cavity of Argas ticks as the Habitat of Spirochetes and Brucella

endosymbionts. Spirochetes were subjected to phagocytosis in the tick's body cavity. Since Ornithodoros papillipes is a natural reservoir and vector of Spirochetes borrelia sogdianum, the author assumes that, in this case too, phagocytosis is of an incomplete nature. The spirochetes change into an avisual form and become intracellular symbionts. This tends to confirm the phenomenon of transovarial transmission of the Borrelia to the next generation reproduced by the infected tick. There are 3 photos, 2 diagrams and 7 Soviet references.

TITLE: Susceptibility of Ixodes ticks to Rickettsia prowazeki

SOURCE: Meditsinskaya parazitologiya i parazitarnyye bolezni, v. 35, no. 3, 1966,  
299-304

TOPIC TAGS: human disease, animal disease, disease vector, rickettsia, ticks,  
Rickettsia prowazeki, experimental infection

ABSTRACT:

Ticks were infected with *Rickettsia prowazeki* by injection or by feeding on infected guinea pigs. Some tick species were more susceptible than others. *Rickettsia* remained in the bodies of ticks infected during feeding for 15 days. *Rickettsia* were found up to 116 days later in ticks infected parenterally, showing that the tick's body provided a favorable environment for growth of *Rickettsia*. Ovarian transmission to progeny did not occur. Infected ticks did not infect healthy guinea pigs by feeding on them, but the guinea pigs could be infected by vaccination with ground tick bodies. TOPIC TAGS: animal disease, tick borne typhus, adaptation, rickettsia, medical experiment, tick, vector, experimental infection, pathogen, rickettsial disease, animal parasite

ABSTRACT:

*Ornithodoros lahorensis* ticks were infected with the tick-borne typhus pathogen *Dermacentrotenus sibiricus* by feeding on infected guinea pigs and by introducing the rickettsia directly into the body cavity. The ticks infected by feeding retained the pathogen for 420 days, and the parenterally infected ticks for 300 days (to the end of the observation period). The infected ticks retained the rickettsia through the subsequent stages of metamorphosis and transmitted them by ovum to their progeny.

Cord 1/2

Parentally infected ticks transmitted the rickettsia to uninfected laboratory hosts (guinea pigs and rabbits) by feeding. The rickettsia were seen in the amebocytes of tick hemolymph by the 4th to 10th day after parenteral infection. *Dermacentroxyenus sibiricus* can be transmitted directly from infected to uninfected ticks by parenteral injection of tracheal matter from the infected ticks. TOPIC TAGS: <sup>18</sup> single crystal growth, <sup>29</sup> germanium single crystal, vapor grown germanium, chemical transport reaction, germanium disproportionation, germanium iodine system, vapor supersaturation

ABSTRACT: Supersaturation at the critical temperature of beginning crystallization is defined and calculated in the same manner for both the general case of crystal growth from the vapor phase and the case of germanium crystal growth by a heterogeneous-germanium disproportionation reaction. Supersaturation is considered an important factor in determining the morphology and defectiveness of a crystal. In the chemical transport reaction

supersaturation is defined as  $\Delta G$  or the ratio  $K_p/n$ , where  $K_p$  is the

2

equilibrium constant of the reaction, n the ratio of partial pressures

$$P_{GeI_4} / P_{GeI_2}^n$$

and  $\Delta G$  the change in isobaric-isothermal chemical potential of the process. A generalized formula is derived for calculating the amount of germanium crystallized in a given volume of a given  $GeI_2 + GeI_4$  mixture, since in the case of a complex chemical reaction supersaturation cannot be directly correlated with crystallization rate and, therefore, cannot be taken as a measure of deviation from equilibrium. The previously reported discrepancies between the temperatures of crystallization and of the source site are confirmed experimentally. It is concluded that germanium crystallization occurs at a temperature substantially lower than the equilibrium temperature, since equilibrium is not reached at the source site. Orig. art. has: 1 table and 9 formulas.

ABSTRACT: The authors investigated the influence of the composition of the vapor phase on the growth rate and on the delineation of the GaAs crystals grown by the open iodide process. At values  $(P_{GaI} + P_{GaI_2})/nP_{As_n} \geq 1$  and small supersaturations, the (111) face increases with minimum velocity, as a result of which there is formed a smooth mirror-like surface of grown epitaxial layers. An increase of the supersaturation leads to the formation of flexible dendrite ribbons with further developed (111) surface. At values  $K = 1$  the relief of the epitaxial layers becomes somewhat more complicated, and thin needle-like crystals appear on the walls of the reactor.

ABSTRACT: The problem of the composition of the gas phase in equilibrium with the solid phase of variable composition of  $Ga_xIn_{1-x}As$  is discussed. The equilibrium of the system is calculated. Solid solutions are obtained by the open iodide method. It is shown that solid solutions become enriched.

ABSTRACT: A study was made of the formation of the surface relief of epitaxial Ge layers as a function of the conditions of their growth by the iodide method in an open tube. The growth rate of (111), (100), (110), and other faces, as a function of the supersaturation, does not change uniformly. At the same layer orientation, different values of supersaturation on the surface of the layers correspond to different growth figures, the faces of which agree with the growth forms of the micro-crystals produced near the substrates. Layers with plane relief of the (111) surface are obtained in the case when the crystallization conditions of Ge correspond to formation of germanium crystals of octahedral form. In all other cases, the relief of the surface becomes more complicated by formation of sharply-peaked or truncated pyramids. [Translation of abstract]

ABSTRACT: The effect of the growth conditions on the perfection of epitaxy Ge layers prepared on melted quartz and on single-crystal Ge is discussed. The equipment used and the method of calculation are described. A method of calculating the real composition of vapor and its derivation from the equilibrium along the crystallization zone is proposed. It was found that a relative oversaturation increases along the crystallization zone at a constant temperature gradient which is based on a sharp change in the degree of transformation in this range of temperatures. The change in supersaturation in various places leads to a variation of dislocation density in the grown layers. In the case of high oversaturation at the end of the crystallization zone a polycrystalline growth of layers takes place. At low oversaturations at the beginning of the crystallization zone on a single-crystal base, "points" are formed which absorb defects during fusing. L. Lezhchuk.

ABSTRACT: The shaping of relief of the surface of Ge epitaxial layers depending on their growing conditions by the iodide method in an open pipe was studied. The rate of growth (111), (100), (110), and other facets varies unequally depending on supersaturation. With the same layer orientation, different growth figures, whose faceting corresponds to the growth forms of near-backing microcrystals, correspond to different surface supersaturations. When Ge crystallization conditions correspond to the formation of octahedral forms, flat-relief (111) layers are produced. In all other cases, the surface relief is complicated by formation of acute-vertex or truncated pyramids. [Translation of abstract]

ABSTRACT: The results are reported of an investigation of the effect of vapor phase upon the rate of growth and faceting of GaAs crystals in the open iodide process.

With  $\frac{P_{Ga,I} + P_{O,I}}{n P_{As,I}} > 1$  and small supersaturations, the (111)-facet grows at a lowest rate which ensures a smooth mirror-like surface of the epitaxial layers grown. At higher supersaturations, flexible dendritic ribbons with a well developed (111)-surface are formed. With  $K = 1$ , the epitaxial-layer relief becomes more complicated, and thin acicular crystals are formed on the reactor walls. I. M., Yu. S.

TITLE:

Junction-Type Silicon Diodes (Ploskostnyye kremniyevyye diody)

PERIODICAL:

Elektricheskvo, 1959, Nr 1, pp 64-68 (USSR)

ABSTRACT:

This investigation concerns the manufacturing process and electric properties of silicon rectifier diodes of the types D 202 to D 205. These are obtained by the method of melting aluminum with the silicon of the n-type. These diodes are obtained from silicon with a specific resistance of 10-30 ohm-centimeters, and show an operating inverse voltage of 100-400 volts and a rectified current of 400 ma. The admissible working temperature of such diodes is + 125°C. These diodes can be used in circuit schemes for rectifying an alternating current with a frequency up to 100 kilocycles. The construction of these diodes is described. It is based on the construction of the germanium diode D-7. Then the volt-ampere characteristics are examined. The principal properties of the diode are expressed by the volt-ampere characteristics (static characteristics) taken at direct

Card 1/3

Junction-Type Silicon Diodes

SOV/105-59-1-16/29

current. The static characteristic and the admissible power greatly mark the quality of the diode. But in order to obtain parameters approaching the working method of rectifier diodes, the characteristic is taken at alternating current in a number of cases (dynamic characteristic). The classification of diodes is given. They are divided in 4 groups according to the magnitude of inverse voltage. The diodes shown here may be also connected in series. Finally, the prospects of development of diodes are illustrated. With the use of Si it will become possible in the near future to obtain diodes for inverse voltages of over 1000 volts, rectifier columns for dozens of kilovolts, large diodes for dozens of amperes, and diodes for special purposes with very small return currents and increased limiting frequency. To obtain diodes with high puncture voltage, it might be of advantage to use the stretching method. This method permits to obtain the fields with different conducting capacities of the crystal during the production of the silicon monocrystal. In the development of diodes, attention is directed more and more to the diffusion method. Some preliminary data on the obtaining of p-n-transitions according to the diffusion method are given
